Document Reconstruction in a Single Column

Dee Specimen and Eli Template

Abstract

This abstract belongs to the single-column paper. The approach is evaluated on three collections of scanned and digital documents. Each page is rendered once and every later stage works on that rendering. Regions are located first and their content is recognized afterwards. The order in which regions are read follows the columns of the page.

1 Introduction

Single-column introduction, first paragraph. The approach is evaluated on three collections of scanned and digital documents. Each page is rendered once and every later stage works on that rendering. Regions are located first and their content is recognized afterwards. The order in which regions are read follows the columns of the page. A block that spans both columns separates the text above it from the text below it.

Single-column introduction, second paragraph. The order in which regions are read follows the columns of the page. A block that spans both columns separates the text above it from the text below it. Captions are attached to the object they describe and are not read a second time. Running headers and page numbers are kept apart from the body of the document. All coordinates are stored in points with the origin at the top left corner.

1.1 Background

Background material introduces the relation Running headers and page numbers are kept apart from the body of the document. All coordinates are stored in points with the origin at the top left corner.

$$E = mc^2 \tag{1}$$

After the equation the background goes on. Each page is rendered once and every later stage works on that rendering. Regions are located first and their content is recognized afterwards. The order in which regions are read follows the columns of the page. A block that spans both columns separates the text above it from the text below it. Captions are attached to the object they describe and are not read a second time. Running headers and page numbers are kept apart from the body of the document.

A further background paragraph fills the page. A block that spans both columns separates the text above it from the text below it. Captions are attached to the object they describe and are not read a second time. Running headers and page numbers are kept apart from the body of the document. All coordinates are stored in points with the origin at the top left corner. The approach is evaluated on three collections of scanned and digital documents. Each page is rendered once and every later stage works on that rendering. Regions are located first and their content is recognized afterwards.

One more background paragraph before the page ends. Running headers and page numbers are kept apart from the body of the document. All coordinates are stored in points with the origin at the top left corner. The approach is evaluated on three collections of scanned and digital documents. Each page is rendered once and every later stage works on that rendering. Regions are located first and their content is recognized afterwards. The order in which regions are read follows the columns of the page. A block that spans both columns separates the text above it from the text below it.

The page is almost full at this point. Regions are located first and their content is recognized afterwards. The order in which regions are read follows the columns of the page. A block that spans both columns separates the text above it from the text below it. Captions are attached to the object they describe and are not read a second time. Running headers and page numbers are kept apart from the body of the document. All coordinates are stored in points with the origin at the top left corner.

The last paragraph of the first page is cut by the page break. The order in which regions are read follows the columns of the page. Its final sentence carries on over the page boundary and

ends only on the second page. Running headers and page numbers are kept apart from the body of the document.

2 Results

Results are summarized in Table 1 and Figure 1; Table 7 does not exist. Captions are attached to the object they describe and are not read a second time. Running headers and page numbers are kept apart from the body of the document. All coordinates are stored in points with the origin at the top left corner.

Table 1: Results on three datasets.

Dataset	Pages	Regions	Accuracy
Alpha	120	1,840	91.2
Beta	310	4,975	88.7
Gamma	95	1,102	93.5

The chart that follows shows the same numbers. Regions are located first and their content is recognized afterwards. The order in which regions are read follows the columns of the page. A block that spans both columns separates the text above it from the text below it.

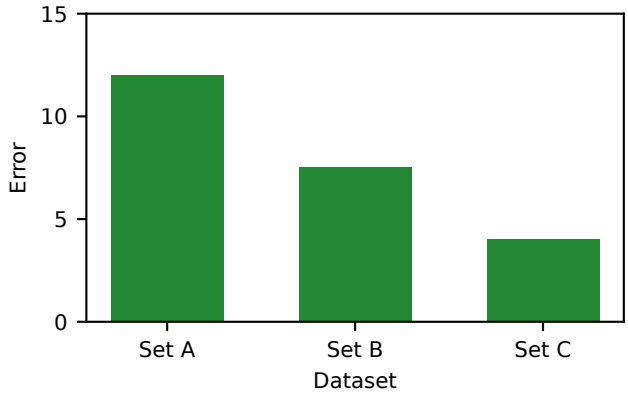

Figure 1: Error on three datasets.

A closing paragraph follows the chart. All coordinates are stored in points with the origin at the top left corner. The approach is evaluated on three collections of scanned and digital documents. Each page is rendered once and every later stage works on that rendering.
